You are looking for detailed information about the characteristics of a diode at a variety of bias and temperature conditions. As a reminder, the diode characteristics are expressed in terms of voltage across the device, current through the device, or power into the device. Circuit basics: A diode is formed by two different semiconductors, p and n, with an energy barrier at the junction of these two layers. When the diode is biased, there is an electric field which drives charge carriers to travel across the junction. This charge (holes in the p-type semiconductor, electrons in the n-type semiconductor) is accelerated in the region near the junction and forms an electron-hole plasma. The plasma gives rise to the current and voltage characteristics of the diode. I've figured out that the "true" forward voltage is the characteristic that determines the voltage drop across the diode at the given forward bias. The "effective forward voltage" is the characteristic that determines the forward voltage drop at a given reverse bias. There are also characteristics of the diode at other bias conditions. Specifically, I've determined that the reverse leakage current through the diode, which is usually denoted "I_{off}", is determined by the effective forward voltage at forward bias. The current through the diode is determined by the effective forward voltage at reverse bias, as long as the diode is not forward-biased. Question 1: At a given bias, at a given temperature, how do I measure the reverse leakage current through a diode? Question 2: At a given bias, at a given temperature, how do I measure the current through the diode? First you need to find a specification of the I
