To determine whether, in a population of rheumatoid arthritis (RA) patients treated with tumor necrosis factor (TNF) antagonists, patients receiving concomitant nonsteroidal antiinflammatory drugs (NSAIDs) were at higher risk for severe gastrointestinal (GI) and serious bleeding events, compared with patients receiving no NSAID. This was an observational cohort study with a nested case-control analysis of the Safety Analytical File (SAF) from the TENOR (Treatment of Early RA with Etanercept) trial. Cases had a GI or serious bleeding event, while controls were matched to cases on tumor necrosis factor antagonist. Cases and controls were matched 1:1 on the dose of celecoxib. Data included were obtained from the start of treatment with celecoxib with the tumor necrosis factor antagonist and concurrent NSAID, to the first event. A total of 200 cases and 400 controls were included. An increased risk for gastrointestinal hemorrhage was seen in patients receiving ≥ 225 mg/day of celecoxib at baseline [odds ratio (OR) 3.83, 95% confidence interval (CI) 1.25-11.5], but not in patients taking ≤ 75 mg/day of celecoxib at baseline, compared with patients with concomitant nonselective NSAIDs (OR 4.17, 95% CI 1.19-14.7).
