Minimal interfering current In electrical engineering, the minimal interfering current is the minimum amount of current needed for the operation of a circuit breaker. A current is called interfering if it produces the effects, which are described in the definition of the term interference (see). When a circuit breaker opens or closes, it passes a short current pulse which induces an effective current in

the rest of the electrical circuit. The length of this pulse should be as short as possible, so as to increase the energy efficiency of the circuit breaker. The current passing through a circuit breaker is measured in amps. For an alternating current, this measurement must be expressed in amperes and for a direct current in amperes and ampere-hours. The minimum current which should be passed to allow for proper operation of a circuit breaker is called the minimum interfering current. According to IEC 60076-2-25 the minimum interfering current for an AC circuit breaker should be and for a DC circuit breaker A voltage is called interferential if it cannot be measured or indicated without making some allowance for interference. It is measured in volts, with the assumption that two 5 V batteries are connected in parallel and with the voltage drop of each battery proportional to its ohm resistance (if the batteries are of the same type). The resistance of the batteries is proportional to their age. The current intensity of a current measurement is proportional to the measured voltage. The minimal voltage which can be indicated without interference is called the minimal interferential voltage. It is measured in volts as well. The minimum

interferential voltage for a circuit breaker opening or closing cycle should be taken into account, when the circuit breaker is dimensioned.
